Cordless phone with answering machine

To illustrate the parts of a cordless telephone, we will show you the inside of this one from General Electric (GE). It was made in 1993 and operated in the 43-50 MHz range.As mentioned above, all cordless phones have a base and a handset. Let's look at these parts individually.Base - The base unit of the cordless phone is plugged into the telephone jack on your wall. If you open up the base and expose the circuit board, you see several components that carry out the functions of the base:Phone line interface - receives and sends telephone signals through the phone line Radio - amplifies signals to and from phone-line interface, user controls and speaker phone (if present) and broadcasts and receives radio signals to and from the handset Power - supplies low voltage power to the circuits and recharges the battery of the handsetPhone Line InterfacePhone line interface components do two things. First, they send the ringer signal to the bell (if it's on the base) or to the radio components for broadcast to the handset. This lets you know that you have an incoming call. Second, they receive and send small changes in the phone line's electrical current to and from the radio components of the base. When you talk, you cause small changes in the electrical current of the phone line, and these changes get sent to your caller. The same happens when the caller talks to you.Radio ComponentsThe radio components receive the electrical signals from the phone line interface and user controls (keypads, buttons). The radio components convert the signals to radio waves and broadcast them via the antenna. Radio components use quartz crystals to set the radio frequencies for sending and receiving. There are two quartz crystals, one for sending signals and one for receiving signals. Remember that the base and handset operate on a frequency pair that allows you to talk and listen at the same time (duplex). The radio components include an audio amplifier that increases the strength of the incoming electrical signals.Power ComponentsA DC power cube transformer supplies the low voltage required by the electrical components on the circuit board. The power components on the circuit board work with the power cube to supply electrical current to re-charge the battery of the handset.In addition to the above components, some bases also have audio amplifiers to drive speakers for speaker phone features, keypads for dialing, liquid crystal displays (LCDs) for caller ID, light-emitting diodes (LEDs) for power/charging indicators, and solid state memory for answering machine or call-back features.Take a look inside the handset next. By Pilar Ethridge There's no reason why you should miss an important phone call while you're away from home. Unfortunately, you might not be able to afford a personal secretary or assistant. For this very reason, answering machines were invented. Once it's installed, callers can leave you voice messages that you can play back at your convenience. That way, whenever you're unable to answer the phone, you won't miss out on a friend's or colleague's urgent message. Find the button that controls playback on your answering machine. It might be as simple as the push of a "Play" button. Or, you might need to dial a code from your phone's handset. Listen closely to your recorded messages one by one. Using pen and paper, jot down the names of those with whom you'd like to correspond. Oftentimes, callers will leave a phone number or other contact information. Once you're ready to return calls, you can refer back to your list of notes. Save or delete messages after listening to them. Your answering machine might have the memory capacity to store several recorded messages, but you should hang on to those that contain important information. If there are several people in your household who use the same phone line, you can save voice messages that are for the others. Check your answering machine messages while you're away from home by setting up remote access on the answering machine itself. You'll have to choose a remote access code that's similar to a password. When you're away, dial your own phone number and wait for the answering machine to pick up. During the greeting, press the "" button, enter your remote access code, and follow the instructions for listening to your messages. By David Weinberg Despite the fact that most American adults own a cell phone, many people still have a landline in their home because of the lower service costs and lack of monthly minute limitations on a landline phone plan. People who want to move around while using their landline phone can use a cordless phone. Cordless phones consist of a base station and the cordless phone itself. The base station is connected directly to a home's phone landline by a standard phone cord. The base station sends and receives voice data with the caller through the landline. It then broadcasts that information directly to and from the cordless phone. A cordless phone will not work if it is outside of the range of the base station. Cellular phones exchange voice data with a cellular data tower. If the cell phone moves outside of the tower's range, the cell phone network automatically transfers the call to another tower so that the user can continue his call as long as he is within range of at least one tower. Cordless phones broadcast at 900 megahertz, 1.9 gigahertz, 2.4 gigahertz or 5.8 gigahertz. The broadcasting frequency is typically printed on the phone or its base station. Other devices in your home may also broadcast on some of the bands. The 2.4 gigahertz band is used by a number of devices that can cause interference, such as wireless routers, and devices that may transmit or receive their own voice data, such as baby monitors. Cellular phones broadcast at 900 megahertz, 1.8 gigahertz or 2.1 gigahertz. These frequency ranges are typically less congested so cell phones are less likely to cause or receive local interference. Cell phone networks identify each cell phone on the network. This allows the network to keep track of each customer's voice and data usage while ensuring that each call is routed properly. Before using a cell phone, you need to activate the device with the cellular service provider either by installing an activated SIM card or by contacting the service providers. Cordless phones do not need to be registered with the phone company. They will work as long as they are within range of their base station and the base station is connected to an active phone line. Some cordless phone base stations will only identify with a specific cordless phone in order to prevent users with the same model of cordless phone from eavesdropping on calls. There is some concern over potential negative health effects caused by cellular and cordless phones. Cordless phones usually remain relatively close to their base stations. As such, they broadcast at a relatively low power compared to cellular phones, which can be miles away from the nearest tower. Cordless phones have a maximum broadcasting power of 10 milliwatts. This rating puts the danger of cordless phones' signals at about 30 times below the level tolerated by the International Commission on Non-ionizing Radiation Protection. Cellular phones can broadcast at up to 250 milliwatts at full power, but most cellular phones decrease their broadcast level to save power when they are close to a cellular tower. Although this is significantly higher than the broadcast power of a cordless phone, it is still within the ICNIRP's safety standards. cordless phone with answering machine for seniors. cordless phone with answering machine - twin handsets. cordless phone with answering machine and speakerphone. cordless phone with answering machine walmart. cordless phone with answering machine 3 handsets. cordless phone with answering machine reviews. cordless phone with answering machine and call block. cordless phone with answering machine canada
